Abstract

An investigation of brake application delays in Australian train brake systems began with a literature review of pneumatic train braking systems. Data located in the review gave examples of brake application delays of pre 1990 designs from the U.K., India and North America. Information on application delays on later Australian designs was scarce. Reading of literature has shown a difference between the Australian and North American control valves in the way the propagation of the pressure reduction rate in the brake pipe is maintained. Control valves of the North American style allow the brake pipe air to be connected for a short time to a small cavity or quick service volume of each valve. The quick service volume is then released to atmosphere. The action of exhausting a small amount of air from the brake pipe helps to ensure a propagation of an adequate pressure reduction rate as it travels to the next valve. Australian control valves rely on the ratio of the volume of brake pipe between control valves and the size of the quick service volume or ‘bulb’ to ensure the propagation of an adequate pressure reduction as it travels to the next valve. The air in a bulb of an Australian valve is not expelled to atmosphere until a brake release is made.

The research explored possible reductions in application delays by utilizing an experimental pipe test rack that included 4 control valves and 120 meters of brake pipe. Experiments with different configurations of exhaust orifices or chokes, valves and branch pipe lengths that supplied the valves gave a record acquired by data acquisition of the timing of each valve and the local pressure drop from a valve or each valve for comparison.

Experiments with exhaust chokes that gave a reduction drop rate in the brake pipe that approached the minimum required to operate a control valve resulted in instability of the application operation of the control valve. The quick service volume of different sizes was included in the experiments to give comparisons in the propagation of the pressure reduction toward the end of a long train. Further increases into the size of the bulb of a control valve to enhance the propagation features toward the end of a long train are discussed. The branch pipe with different diameters from 12 mm to 20 mm and lengths from 160 mm to 800 mm when fitted to an adaptor pipe bracket were investigated and results show that larger diameters gave larger gulps in the brake pipe.

Other components that were studied included the pipe bracket that is fitted on some control valves. The pipe bracket and isolation cock was found to add 282 mm of additional length to the air path and while not changing the operation of the valve, the results showed a smaller drop in local pressure in the brake pipe to assist the pressure reduction rate than shown in valves without pipe brackets.

Ripley. I *Development of the Railway Air Brake Triple Valve in America and Australia* June 2003
Acknowledgments

This thesis was possible due to the scholarship awarded by the Rail Co-Operative Research Centre and is gratefully acknowledged for the period of the research program.

Acknowledgement is extended to Dr Colin Cole as the principle supervisor and to Dr Masud Khan co-supervisor for assisting with advice in experimental testing and reading of this thesis.

Central Queensland University engineering workshop staff Mr Gary Hoare and Mr Ian Major are both gratefully thanked for the assistance in the setting up of the brake pipe test rig in the heavy testing laboratory at CQU.

The assistance and use of braking equipment from Queensland Railway is acknowledged as is the suggestions and advice from Mr Barry Payne and Mr David Fuhrmeister.

Involvement by Australian rail industry personnel including Mr Stephen White and Mr Bruce Sismey for the information supplied is acknowledged.

Westinghouse Australia for the advice and information on their braking system is acknowledged as was the support by Mr Kevin Heslop.

Further thanks must go to my brother Robert and my sister Nanette for their personal help over the period of this project.
Declaration

I declare to the best of my knowledge this thesis does not contain any material previously published or written by another person except where due reference is made in the text. The contents of this thesis have not been included in any other work submitted by the author for another degree or diploma at any other tertiary institution.
