Appendix 6. Summary table of environmental parameters measured at 149 macrobenthic sampling station in Port Curtis during 2002. All measures presented for water temperature (°C), salinity (ppt), dissolved oxygen (mg/L) and pH, are means derived for the water column at each station (1m intervals), and have been standardised by daily readings at navigation buoy A8. Secchi depth (m) and measures of total chlorophyll (µg/L) are individual surface measurements, but have also been standardised by daily readings at buoy A8. Percentage organic carbon measures are given for surface sediments at all stations, and are means derived from three replicate grabs.....	94

Summary

Spatial patterns in benthic infaunal community structure of Port Curtis estuary (north-eastern Australia) were determined from quantitative grab samples and examined in relation to environmental variables. A total of 149 riverine, estuarine and open coastal stations were sampled during the survey, and 5744 individuals and 466 species identified. Filter-feeding organisms (primarily polychaetes, molluscs and crustaceans) dominated the bedforms, and accounted for 50% of the total species abundance and 30% of the total species richness. Most taxa were uncommon, and 98% of species individually represented less than 2% of the total abundance. Distributional patterns in total species richness and abundance were highly correlated, and both parameters varied significantly with sediment structure. Numbers of species and individuals were typically highest in coarse-sand and gravel sediments, and lowest in fine, well-sorted, sands. Cluster analysis of species abundance data revealed nine community groupings characterised by small species subsets with restricted distributions. These groupings were found to be primarily related to measures of depth, salinity, dissolved oxygen and sediment structure. Not all variation in community structure was explained by these environmental variables, and it is likely that other unmeasured factors play an important role in determining benthic faunal composition in the estuary.

1. Introduction

Macrobenthic communities are important functional components of estuarine ecosystems. These organisms play a significant role in the diets of many shorebird and fish species, and can profoundly influence the abundance and species composition of these tertiary consumers (Bottom and Jones, 1990; Skagen and Oman, 1996; Stillman et al., 2000). Macrofauna also play an integral role in the recycling of nutrients, and conservation of water quality within estuarine systems (Harris, 1999; Peterson and Heck, 1999). Understanding benthic community structure, and the factors underpinning it, is therefore essential to the better management of these waterways.

Multiple biotic and abiotic factors are reported to affect the distributional patterns of shallow-water benthic fauna. Major physical influences include depth (Gray, 1981), sediment structure (Butman and Grassle, 1992; Sundberg and Kennedy, 1993), salinity (Gaston and Nasci, 1988), and hydrology (Pearson and Rosenberg, 1987), while important biological factors include predation (Peterson, 1979; Kneib, 1991), competition (Wilson, 1990; Peterson and Andre, 1980) and recruitment (Butman, 1987; Olafsson et al., 1994). Estuarine benthos may also respond to a range of human-induced impacts where present, including organic enrichment (Pearson and Rosenberg, 1978), chemical pollution (Warwick, 1988) and commercial fishing activity (Currie and Parry, 1996). Because the list of structuring forces is potentially very long, and varies according to characteristics of the estuary, generalizations on the dominant structuring processes for estuarine benthos are often difficult to define.

Relatively few studies undertake large scale field assessments of the defining characteristics of soft-sediment habitats (Constable, 1999). Previous research in Australia has concentrated on highly modified and populated estuaries (Stephenson et al., 1974; Poore et al., 1975; Coleman et al., 1978), and principally examined factors influencing the distributions of individual species. More recent studies have examined the importance of environmental factors in explaining patterns in community structure between less populated regional estuaries (Edgar et al., 1999; Hirst, 2004). These temperate water studies have generally concluded that salinity predominantly structures diversity and community composition of estuarine macrofauna.

The importance of salinity in structuring estuarine benthos in non-temperate regions is unclear. Latitudinal variation in climate, notably rainfall, runoff and net precipitation, exert major controls over the salinity regimes of estuaries (Heggie and Skyring, 1999). Models derived for temperate regions may therefore have little relevance in tropical and sub-tropical provinces. Additionally, patterns defined for Australian estuaries may not necessarily conform with those elsewhere, particularly given the continents peculiar biogeography and unusually low rainfall characteristics (Harris, 2001). Unfortunately, tropical and subtropical macrobenthos are rarely studied (Alongi, 1990; Hutchings, 1999), and virtually no published data are available to confirm or challenge current temperate water paradigms.

In an effort to redress the paucity of information for macrobenthos in non-temperate zones, the present study concentrates on structural forcing in a sub-tropical estuarine system. Specifically, it examines the composition and distribution of benthic infauna and their relationships with a range of environmental factors. Relative contributions of each environmental factor to observed spatial patterns are identified, and key determinants discussed in a regional and global context.

2. Materials and methods

2.1 *Macrobenthos*

Spatial variations in the benthic community structure of Port Curtis were determined from quantitative grab samples collected at 149 sampling station. These stations were arranged on 2 adjacent grid arrays (1.5km^2 - inner harbour; 3km^2 - outer harbour) that extended to cover the entire body of the port (Fig. 1). This sampling design included riverine, estuarine and open coastal reaches of the waterway, and encompassed bedforms of varying depth throughout the study area.

All sampling was conducted over a seven-week winter period (17 July to 3 September 2002) using two vessels with customised grabs. A light-weight 0.1m^2 van Veen grab was primarily used for sampling soft muddy sediments in the inner harbour, while a heavier 0.1m^2 Smith McIntyre grab was employed for sampling firm sand and shell-sand substrates in the outer harbour. Except for differences in weight, both grabs were armed with identical sized buckets and collected similar volumes of sediment. However, to limit variation in efficiency between grabs, all samples were weighed following removal of the supernatant liquid and only those containing 10kg or above retained.

A total of 3 replicate grabs were collected from each of the 149 sampling station with the skipper holding the vessel on site without anchor. Navigation to all stations was undertaken with a differential GPS that provided an accuracy of 3m or less in 95% of fixes (Appendix 1). All grabs collected were sieved on a 1mm mesh screen and the fauna retained preserved in 5% formaldehyde solution. This fauna was later sorted in the laboratory to the highest taxonomic level (generally species) before being counted (Appendices 2, 3 & 4).

2.2 *Sediment*

Two sediment sub-samples (70ml and 10ml) were retained from each replicate grab sample prior to sieving. These fractions were collected from the surface layer by scraping an open vial across the top of each sample. The sediments collected were snap-frozen and stored at -20°C , before being examined for size structure and organic carbon content.

The 70ml sediment sub-samples were wet-sieved through an agitated stack of Endecott sieves, with apertures of 2mm, 1mm, 500 μm , 250 μm , 125 μm and 63 μm . Fractions retained on each sieve were oven dried (105°C) and weighed, and their

masses used to estimate the median diameter of the sediment in each grab (Appendix 5). This parameter was subsequently used to investigate relationships between faunal composition and sediment structure.

Correlations between faunal composition and the amount or organic material in the sediments were also investigated. 10ml of sediment from each grab was oven dried (105°C for 24h) to remove all moisture. The sample was then ground to a talcum-power consistency in a mortar and pestle, and the carbonates removed by acid digestion (20ml, 0.5M HCl for 1h). Following washing in distilled water the sediment samples were oven-dried (105°C for 24h) and weighed. The samples were then ashed in a muffle furnace (660°C for 1h), before being reweighed. The percentage organic carbon content of each grab sample was estimated from the loss in weight following ignition.

2.3 Water chemistry

A comprehensive water quality survey was undertaken at the same time as the grab sampling study. Measures of water temperature, salinity, pH and dissolved oxygen content were collected from each of the 149 sampling station using an automated water quality analyser (YeoKal 611™). This instrument was preset to acquire data at 1m intervals, and was lowered on a weighted cable through the water column at each station immediately prior to grabbing. Turbidity of the water column at each sampling station was measured using a 30cm diameter Secchi disk. This was lowered on a metered rope beneath the research vessel until no longer visible, and the depth at which this occurred was recorded. Measures of total chlorophyll concentration were also determined for surface waters at each sampling station following the procedures detailed in ISO 10260 (1992).

Because it was recognised that sampling of water quality parameters would occur over an extended period (~7weeks), a control site was established to standardise temporal variation. This control site was located at channel marker A8 near the centre of the study area, approximately 500m north-east of the mouth of Auckland Creek (Fig. 1). Measures for all water quality parameters under study were collected from this location each morning before sampling elsewhere. All results presented here have been standardised to water quality conditions observed on the first day of sampling (17 July 2002).

2.4 Data analysis

A geographical information system (GIS) was employed to characterise and display spatial trends in environmental data. Physical, chemical and biological attributes for each sampling station were interpolated using an inverse distance weighting (IDW) algorithm (Cressie, 1993), and series of predictive maps constructed. These maps were used to visualise discontinuities between homogeneous regions and highlight patterns of similarity between variables. Relationships between each environmental variable were subsequently tested using Pearson's correlation coefficients.

Variations in benthic community structure between the 149 Port Curtis stations were examined using Bray-Curtis dissimilarity measures (Bray and Curtis, 1957). This dissimilarity measure was chosen because it is not affected by joint absences, it gives more weighting to abundant than rare species, and it has consistently performed well in preserving ecological distance in a variety of simulations on different types of data (Field *et al.*, 1982; Faith *et al.*, 1987). Single square root transformations were applied to the data to prevent abundant species from influencing the Bray-Curtis dissimilarity measures excessively (Clarke and Green, 1988; Clarke, 1993).

Multivariate analyses were conducted using the computer package PRIMER (Clarke and Gorley, 2001). Hierarchical agglomerative clustering was used to group sites according to their infaunal community composition, and a similarity percentage test (SIMPER) conducted to determine those species contributing most to within and between site groupings. The extent to which measured environmental variables (temperature, salinity, pH, DO, turbidity, chlorophyll, sediment structure and organic carbon) could account for observed community groupings was further tested using the BIOENV routine of Clarke and Ainsworth (1993).

3. Results

3.1 Physical characteristics

3.1.1 Bathymetry and hydrology

Port Curtis estuary refers here to the body of water extending between the mainland and Curtis and Facing Islands, and includes adjacent coastal waters (Fig. 1). Collectively the waterway covers an area of more than 200 km² and includes a network of creeks, inlets, shoals and channels. Water circulation patterns around these features are complex but primarily governed by a large tidal regime (>5m). Tidal current velocities vary depending upon location, but are typically highest (>5 knots) in the deep arterial channels that extend the length of the inner harbour. Most tidal exchange occurs across the wide southern entrance to the port and the deepwater channel (<20m) that runs between the mainland and Facing Island. The northern entrance between Curtis and Facing Island is, by comparison, much shallower (<3m) and narrower (<3km) and receives relatively lower volumes of water during each tidal cycle. A third tidal opening at the Narrows, in the northeast of the estuary, forms a watershed. Shallow channel beds are exposed here during low tides, and water exchange with the adjacent Fitzroy River estuary is relatively low and periodically restricted.

Approximately one-third of the estuarine bedforms are located above the mean low-water mark and may be classified as intertidal. These habitats are most extensive in the wave protected waters of the inner harbour, and typically occur as gently sloping nearshore mudflats. These mudflats often support sparse seagrass beds, and are characteristically fringed by mangrove and saltmarsh communities at their upper tidal limits. Nearshore gradients in the outer harbour are, by comparison, much steeper and intertidal habitats here are generally represented by narrow sandy beaches and occasionally small rocky outcrops. Neither of these intertidal substrates supports a prolific floral growth, and presumably reflects relatively higher levels of exposure to wave erosion.

Shallow sub-tidal sandbanks (<5m depth) comprise a further third of the bedforms in the port. These banks are primarily a feature of the outer harbour, and extend through much of the waters to the east of the southern entrance. Here the banks present a significant natural barrier to prevailing south-easterly swells, and so provide a degree of protection for inshore waters and coastal mangroves on the mainland side of the entrance. The residual port bedforms occur over a wide depth range (5 - 21m) and are principally associated with channel features in the inner harbour. These axial channels are generally shallowest in the upper reaches of the estuary, and become progressively deeper towards the southern entrance. In the outer harbour, sand banks gradually shelf offshore towards the northeast, and bedforms in this region of the estuary are located in the greatest depth of water.

3.1.2 Temperature

Marked differences in seawater temperature were observed across Port Curtis during the winter of 2002 (Fig. 2). These differences were most pronounced at the mouth of the Calliope River, where temperatures were more than 6°C higher on average than the rest of the estuary. The elevated water temperatures at this location are principally due to heated seawater discharges from a coal-fired power station, and thermal pollution from this source appears to be pervasive and influence much of the inner harbour. Less pronounced spatial trends in temperature are also evident in the outer harbour, although patterns for this region of the port are largely the result of depth-related temperature gradients. All estimates of temperature presented were averaged for the water column at each station, and therefore integrate any depth-related gradients in temperature. While depth-related temperature differences were negligible in the well-mixed waters of the inner harbour, a strong thermocline ($\Delta 1.3^{\circ}\text{C}$) was found to occur in the deeper waters of the outer harbour, and is principally responsible for the apparent decline in temperature with increasing distance offshore.

3.1.3 Salinity

Port Curtis is typically subject to large volumes of freshwater inflow and reduced salinities during the wet summer months, but generally receives little freshwater inflow during winter. Accordingly, marine conditions generally prevail in the water column through winter. In the present winter survey salinities were found to range between 35.79 and 37.36 ‰, and were broadly consistent with marine conditions. In general, salinity was greatest in the upper reaches of the port but gradually declined towards the outer harbour (Fig. 2). This small, but subtle, trend in salinity is consistent with reduced exchange and increased residence times for water in the upper harbour, and is almost certainly a function of evaporative forcing.

3.1.4 pH

Because measures of pH are strongly coupled with salinity (Table 1), spatial patterns in pH across Port Curtis closely mirror those for salinity. Values of pH were most acidic (7.79) in the upper reaches of the estuary but progressively increased in alkalinity towards the outer harbour (up to 8.47) (Fig. 2).

3.1.5 Dissolved oxygen

Dissolved oxygen concentration in Port Curtis varies inversely with temperature (Table 1). Accordingly, the distributional map of dissolved oxygen concentration displays a number of features consistent with spatial pattern in temperature (Fig. 2). In particular, the map shows that oxygen concentration levels are typically depressed in the heated waters of the inner harbour (3-5mg/L). Additionally, it shows that oxygen concentrations are greatest in the cold channel waters that extend between Facing Island and the mainland (7-8mg/L). This inverse relationship between dissolved oxygen concentration and temperature holds for much of the harbour, but is less pronounced in the open coastal waters of the port. Inconsistencies in this relationship are highlighted by the presence of oxygen saturated and oxygen depleted water of similar temperature off Facing and Hummock Islands respectively.

3.1.6 Turbidity

Secchi-disc measurements taken during the winter of 2002 demonstrate that water clarity, and by inference turbidity, are highly variable across the port waters (Fig. 2). Visibility ranged from 0.3m to 14.5m, but was generally lowest in the sheltered waters of the inner harbour and greatest offshore. This meso-scale gradient in turbidity is largely forced by tidal mixing, and broadly reflects the availability and distribution of fine sediments. Most fine sediments principally occur on intertidal banks in the inner harbour, and accordingly these wetlands are also sites of highest turbidity (Narrows, Targinie, southern Curtis Island; Figs. 1 & 2). By comparison, channels adjacent to the intertidal regions of the inner harbour are much less turbid. This observation is consistent with the knowledge that swift tidal currents operate through these channels and presumably promote bottom scour and limit settlement of fine particulate material. Some winnowing and transport of fine intertidal muds by channel currents is predicted, particularly during spring tides, and presumably contributes to the generally higher turbidity of the inner harbour.

3.1.7 Chlorophyll

Measures of chlorophyll concentrations during this winter survey were highest in shallow nearshore waters to the east of the southern entrance, and it appears that the water column here is a major site for primary production (Fig. 2). As previously described, this region of the port is the locus for most tidal exchange, and nutrient out-welling and reduced turbidity here presumably provide favourable conditions for algal growth. Elsewhere in the outer harbour, chlorophyll concentrations are generally high (>2 mg/L), except at a small number of stations to the east of Facing Island. By comparison, measures of total chlorophyll are generally lower through most reaches of the inner harbour. This broad-scale gradient in chlorophyll concentration between the inner and outer harbour, appears to be largely underpinned by differences in water chemistry. Variations in chlorophyll concentration were found to vary significantly in response to salinity, pH and dissolved oxygen levels (Table 1). Accordingly, observed spatial differences in chlorophyll concentration possibly reflect differential tolerances by algal species to these parameters. It is, of course, also likely that observed spatial differences vary in response to other unmeasured variables.

3.1.8 Sediment

Bottom sediments in Port Curtis estuary were highly variable over relatively small distances (<1.5km), and median size classes ranged from silt and mud, through sand, to coarse-sand and gravel. Textural coarseness was found to increase significantly with depth (Table 1) consequently geographical patterns in sediments broadly reflect patterns in port bathymetry (Figs. 3 & 1). Four sedimentary facies were identified in the port. “Silts and muds” (<63 μ m diam.) were largely restricted to protected intertidal flats in the inner harbour. “Fine sands” (0.06-0.25mm diam.) were found in shallow banks between Curtis and Facing Islands, and more extensively through much of the outer harbour north of Hummock Island. “Medium sands” (0.25-0.5mm diam) generally flanked channels through much the inner harbour, and also predominated in shelving waters through the outer harbour. While “Coarse sands and gravels” (>0.5mm diam.) were primarily found in the scour holes of arterial channels and entrances, and additionally around fringing reefs (Sable Chief and East Point Ledge) on the eastern side of Facing Island.

3.1.9 Organic carbon

Total organic carbon content of sediments in Port Curtis was spatially variable (2.9 - 18.7%), and distributional patterns for this parameter closely followed trends in sediment structure (Fig. 3). Elevated levels of organic carbon ($\geq 10\%$) were generally associated with medium and coarse sediments, while low levels of organic carbon (<10%) were predominantly linked with fine, unconsolidated, sands near the northern and eastern entrances to the port. Elevated levels of organic carbon were additionally prevalent in fine muds and silts in the upper harbour.

3.2 Faunal characteristics

3.2.1 Faunal composition

A total 466 species and 5744 individuals were found in the 447 grab samples collected during this study. Polychaetes, molluscs and crustaceans together accounted for more than 74% of the individuals and 84% of all species collected. Other less common taxa encountered included echinoderms, chordates, cnidarians, echiurans, sipunculids, pycnogonids, nemerteans and brachiopods.

Filter feeding organisms dominated the infaunal communities in Port Curtis, and accounted for more than 50% of the total abundance and nearly 30% of the total species richness. Deposit feeding organisms were also common, and represented more than 24% of the total abundance. The same group was also the most diverse, and accounted for 32% of the total species compliment. Other trophic groups including predators, scavengers, grazers and parasites, were rarely encountered. Collectively these feeding groups represented less than 25% of the total number of individuals, and less than 39% of the total species diversity.

The tube building anemone *Ceriantharia* sp. 3 was the most abundant species found during the study. This relatively large (3cm), suspension feeding organism represented more than 14% of the total infaunal abundance, but was poorly distributed and present at less than 4% of the sampling stations. The bivalve mollusc *Mactra abbreviata* was the next most common species overall, and accounted for 12% of the combined abundance. This organism was much more widely distributed than the anemone, and was collected at more than 27% of the sampling stations. A further four species (including the bivalves *Leionuculana superba* and *Grafrum transversarium*, the ascidian *Ascidia sydneiensis*, and the polychaete worm *Eunice vittata*) were represented in 2-4% of the total. All other organisms (98% of species) were collected infrequently, and individually contributed less than 2% to the total abundance.

Species richness and abundance were highly correlated and both metrics varied significantly with sediment structure (Table 1). Distributions patterns for richness, abundance and sediment structure were therefore broadly similar (Fig. 3). In general, coarse-sand and gravel sediments supported the greatest number of species and individuals, while fine, well-sorted, sands support the least. Medium sands and silty muds, in contrast, supported intermediate densities of species and individuals. Highest species diversity (54 spp.) was recorded for a biogenic, gravel, sample collected from a channel bed at the southern entrance to the port. Other ‘hotspots’ of biodiversity included Jenny Lind Bank (45 spp., a fringing reef north of Hummock Island), North Entrance (39 spp.) and the Narrows (31 spp.).

3.2.2 Community structure

Nine station groupings were separated by cluster analysis of species abundance data (Fig. 4), and their corresponding distributions plotted (Fig. 5). These groupings closely reflected differences in depth and habitat type within Port Curtis (Fig. 1). Group I comprised 8 stations characterised by shallow, low-diversity, fine sands (primarily located on shoals around the southern entrance to the harbour). Group II contained 6 stations chiefly defined by medium-coarse, low-diversity, sands (mainly found in shelving bedforms in the outer harbour). Group III contained 2 stations, both of which supported fine, sandy-mud, substrates and low species diversity (located in shallow nearshore water of the inner harbour). Group IV consisted of 5, low-diversity, muddy, stations (primarily shallow subtidal and sited near creek mouths in the upper harbour). Group V embraced 22 stations characterised by intertidal, low-diversity, muds (principally occurring in nearshore waters of the inner harbour). Group VI contained 6 intertidal stations with low-diversity, medium sands (principally located in nearshore reaches of the outer harbour). Group VII consisted of 16 shallow, subtidal, stations with low-diversity, fine-medium sands (primarily located in the outer harbour). Group VIII contained 43 shallow, subtidal, stations with high-diversity fine-medium sand and mud (primarily on channels banks). And Group IX, contained 41 deep, subtidal, stations with high-diversity, coarse sand and gravel bedforms (located mainly in channel beds).

SIMPER analysis was undertaken to assess which species contributed most to similarities within and differences between the nine station groupings. Abundances of the 36 species contributing $\geq 5\%$ to within-group similarity or between-group dissimilarity for at least one of the nine groupings are given in Table 2. The average within-group similarity ranged from 10 to 30%, and between group dissimilarity ranged from 93 to 99%. Most station groups (I-VII) were characterised by relatively small subsets of species with restricted distributions. Other groups (VIII & IX) with generally higher diversity were differentiated by varying proportions of co-occurring species.

The PRIMER routine BIOENV was used to assess the correspondence and significance of environmental data to the nine station groupings. The best fit was with sediment structure ($\rho_w = 0.31$), which in combination with depth, salinity and dissolved oxygen and gave a best fit of $\rho_w = 0.38$. The remaining variables (temperature, pH, turbidity, organic carbon and chlorophyll) were apparently unrelated to any pattern in station groupings ($\rho_w < 0.08$).

4. Discussion

Data presented in this study provide very strong indications that sediment structure is a primary factor underlying the distribution, abundance and community composition of benthic infauna in Port Curtis estuary. Species richness and abundance were found to be highly correlated with median grain size, and coarser sediments generally supported increased numbers of species and individuals. Strong correlations between sediment grain size and biotic composition have been previously demonstrated in many estuarine and shallow coastal environments (Sanders, 1958; Dayton, 1984; Currie and Parry, 1996; Coleman et al., 1997; Snelgrove, 1999), although observable patterns are frequently contradictory. In part, this may reflect differences between studies in the range and diversity of sediments examined, but may also reflect the effects of other factors, in particular hydrodynamic processes which affect the distribution of both sediments and fauna (Snelgrove and Butman, 1994).

Tidal circulation patterns in the Port Curtis estuary are complex and sediment composition is variable over small spatial scales (Conaghan, 1966). As a result, sedimentary facies are patchy and homogenous sediments are often geographically isolated. Patterns in benthic community structure are nonetheless closely matched with patterns in sediment texture, particularly in the inner harbour. Three community groupings identified from cluster analyses (V, XIII & IX) displayed a

high affinity with the key sedimentary classes occurring in the inner harbour, and collectively represented most sedimentary features in this region of the estuary. Specifically, Group V was intimately associated with muddy intertidal deposits and characteristically supported high densities of filter feeding bivalves (*Mactra abbreviata* and *Azorinus* spp.). Group XIII, corresponded largely with medium-sand deposits occurring on channel banks, and typically supported low densities of deposit feeding bivalves *Leionuculana superba*. While Group IX, was closely related to coarse-sand and gravel sediments present in channel beds, and typically supported large numbers of sedentary filter feeders (including the ascidian *Ascidia sydneiensis* and clam *Placamen tiara*). In contrast, sediment-community relationships were less well defined in the outer harbour. Sediment structure is relatively more uniform in the outer harbour, and this region of the estuary generally supports a more diverse and patchy collection of communities. This finding suggests that sedimentary composition may be less important in structuring benthos in open coastal zones than it is in sheltered estuarine waters.

Water depth was also as an important factor in determining the community structure of benthos in Port Curtis, and largely explained the separation of discrete intertidal and subtidal communities in both the inner and outer harbour. For example, community analysis revealed that Group V (intertidal, inner harbour, mud) and Group VI (intertidal, outer harbour, medium sand), were more similar to one another than to any other community classified. These differences stem from disproportionately higher abundances of a few species in the intertidal (the polychaete *Glycera* sp.1, the bivalve *Donax veruinus* and the hermit crab *Diogenes guttatus*), and presumably reflect increased physiological tolerances in these species for life between the tide marks. While the significance of water depth for benthic communities is widely recognised in benthic ecology (Gray, 1981), depth *per se* is not expected to be a causal factor in their distribution, at least in the subtidal zone. This is because depth will co-vary with a number of other environmental variables (in this study, salinity, pH, turbidity and sediment structure), that may also affect the distribution and community composition of benthic species.

Salinity is one of the most widely studied environmental factors in estuaries, and is frequently cited as a major factor in limiting the distribution of benthic fauna (Day, 1981; Gaston and Nasci, 1988; Edgar et al., 1999; Hirst, 2004). Because marine organisms display differential tolerances to salinity, variations in this parameter can promote marked shifts in species representation and community structure. Water salinity in Port Curtis varied little over the entire waterway (< 2 ‰), however a saline gradient was evident, and salinities in the inner harbour were generally higher than those in the outer harbour. Despite the small level of variation, BIOENV analysis revealed that salinity was a significant factor in determining benthic community structure in the estuary. This result is largely explained by the presence of distinct breaks in faunal composition in accordance with discrete salinity ranges. For example, one suite of communities identified from cluster analysis (Groups I, II, VI & VII) invariably occurred in waters that were fully marine (35.7 - 36.4 ‰), while a second suite (Groups III, IV and V) were present only in salinities above 36.4 ‰. A third suite (Groups VIII & IX) spanned the complete range of salinities measured in the estuary (35.7 - 37.4 ‰) and generally weakened correlations between fauna and salinity. As a consequence, salinity was recognised as only a minor factor structuring benthos in the estuary (<9% of variation explained).

In addition to sediment, depth and salinity, dissolved oxygen content had a significant influence on benthic communities in the estuary. But like salinity, dissolved oxygen content was inconstantly matched with many community facies and the relationship was relatively weak. Benthic organisms are dependent on dissolved oxygen for processes of respiration and metabolism, and low levels can result in extinctions of species and changes in community composition (Deeley and Paling, 1999). In Port Curtis, dissolved oxygen concentrations were relatively high (3.8 to 8.2 mgL⁻¹), and generally in excess of levels considered hypoxic (<2 mgL⁻¹), or indeed levels at which causal changes in benthos have been previously

documented (Gaston et al., 1998). These relatively high oxygen concentrations are consistent with good tidal mixing and water circulation within the estuary, and distributional patterns in dissolved oxygen broadly reflect areal differences in hydrology. This is demonstrated by the fact that well mixed channel waters in the estuary invariably support the highest oxygen concentrations, while waters in many isolated creeks and inlets support relatively lower concentrations. By exception, a large area of oxygen depleted water was found to occur in well mixed oceanic waters in the outer harbour, north of Hummock Island. However the same area was also the locus for elevated levels of chlorophyll, and it appears that low DO here is the net result of nutrient out-welling and localized oxygen consumption by algae.

A range of other environmental variables considered in this study (including temperature, turbidity, chlorophyll and organic carbon) had no apparent direct influence on macrobenthic community structure in the estuary, and may be considered unimportant on a system-wide scale. However, indirect and interactive effects of these and other variables may well have produced the observable patterns in benthos. Indeed, as only a third of the variation in community structure was collectively explained by sediment, depth, salinity and dissolved oxygen, it is clear that other mechanisms are important in determining the distribution and composition of macrobenthos within the estuary. Unmeasured water circulation patterns for example can influence benthic communities in several ways. Most importantly, they modify other water column processes such as near-bottom flow that bring food and new recruits to the community (Ramey and Snelgrove, 2003). In addition they may affect the structure and stability of bedforms and their suitability as sites for colonization (Thrush *et al.*, 1996). All of these processes act in concert with post-settlement processes such as disturbance (Wooden, 1999), predation (Thrush, 1999) and competition (Peterson and Andre, 1980) to influence patterns in abundance and distribution. Unfortunately in the absence of any supportive experimental studies, it is unclear just what the contributions of such factors are for benthos in Port Curtis.

Benthic fauna are considered important indicators of water quality and are used in a variety of monitoring programs to assess overall estuarine health and to determine the effects of pollution (Gray and Christie, 1983; Warwick, 1993). This is largely because benthic organisms are relatively non-mobile and tend to integrate effects of pollutants over time. As different communities may respond in different ways to the effects of a disturbance, natural spatial variation in benthos can often confound attempts to detect the effects of a disturbance. The identification and monitoring of similar but geographically discrete communities (spatially uncorrelated by disturbance or recruitment processes) is therefore a central element of good survey design. Like many estuaries world-wide, Port Curtis is the locus of a growing human population, with increasing demands on goods and services from the catchment. As the population and industries of Port Curtis region continue to grow, so too does the potential for environmental degradation. Considerable visible changes to the coastline of Port Curtis have occurred in recent times, and over 650 hectares of mangroves and 990 hectares of saltmarsh have been lost to reclamation or environmental stress since the 1940's (QDEH, 1994). Concomitant changes to water quality and the ecology of the estuarine biota are largely undetermined, as few quantitative historical data exist. If future developments within the region are to be implemented in an environmentally responsible manner, it is necessary that the estuarine resources are adequately documented and their conservation values assessed. To this end, the present study has added considerably to our knowledge of the kinds of invertebrate organisms inhabiting Port Curtis, and the mechanisms underpinning their distribution and abundance. Moreover, this study has provided a reference point for future benthic studies in the estuary, and a framework for developing more robust monitoring designs for environmental effects at spatial scales relevant to prospective human development.

Acknowledgements

A large number of people have made significant contributions to this project. In particular we are grateful to Cpt. Norm Fraser and the skipper and crew of the Queensland Department of Transport vessel *Bruce Whiteman* for their invaluable operational support. We are also most grateful to the following Centre for Environmental Management staff for undertaking much of the field work associated with this project; Rod Johnson (field supervisor), Andrew Davis (coxswain), Damon Shearer and Vikki Rogers (deckhands). Our thanks also go to Jill Campbell, Shona Marks, Natalie Callanan, Karen Boundy, Kelly Jacobs, Christopher Hackney, Clayton Plummer, Laura Mears, Richie Binder, Scott Coxon, Carl Boundy, Luke Wotton, Pam Malyszek, Sarah Young and Monique Case for sorting and provisionally identifying the large volume of biological material collected during this study, and for undertaking the sediment analyses. Species identifications for several key taxonomic groups were confirmed by research staff at the Australian Museum, and we are most grateful to Dr. Penny Berents for co-ordinating this work. Hydrographic survey data for the port was made available by the Queensland Department of Transport and the Australian Department of Defence, and its provision is greatly acknowledged. This research project was initiated by Dr. Alistair Melzer and funded by a Research Infrastructure Grant to the Department of Arts Heath and Sciences, Central Queensland University.

Table 2. Abundance (N per 0.3m²) of infaunal species in 9 regions of Port Curtis identified from hierarchical classification of species/abundance data. Species listed were identified from SIMPER analyses as contributing ≥ 5% to the similarity within and dissimilarity between regional groupings. Those species indicative of each regional grouping (contributing ≥ 5% to the total similarity within a group) are highlighted in bold. Species are ranked in order of decreasing abundance across all station groupings.

Mollusca	Gastropoda	Rissoidae	grazer	Rissoidae 1	G245
Mollusca	Gastropoda	Terebridae	predator	Gastropoda 171	G209
Mollusca	Gastropoda	Triphoridae	predator	Notosinister maculosa	G251
Mollusca	Gastropoda	Trochidae	grazer	Euchelus atratus	G254
Mollusca	Gastropoda	Trochidae	grazer	Trochidae 18	G258
Mollusca	Gastropoda	Turbanellidae	predator	Tudivasum armigera	G293
Mollusca	Gastropoda	Turbinidae	grazer	Gastropoda 113	G154
Mollusca	Gastropoda	Turbinidae	grazer	Gastropoda 153	G191
Mollusca	Gastropoda	Turbinidae	grazer	Gastropoda 162	G200
Mollusca	Gastropoda	Turritellidae	grazer	Turritellidae 1	G272
Mollusca	Gastropoda	Turritellidae	grazer	Turritella sp. 1	G273
Mollusca	Bivalvia	Alloididae	suspension	Corbula (Serracorbula) crassa	B1
Mollusca	Bivalvia	Arcidae	suspension	Arcidae 1	B2
Mollusca	Bivalvia	Arcidae	suspension	Arca (Arca) navicularis	B221
Mollusca	Bivalvia	Arcidae	suspension	Arcidae 3	B4
Mollusca	Bivalvia	Arcidae	suspension	Trisidos tortuosa	B5
Mollusca	Bivalvia	Arcidae	suspension	Bivalvia 35	B62
Mollusca	Bivalvia	Cardiidae	suspension	Ctenocardia (Ctenocardia) sp.	B220
Mollusca	Bivalvia	Carditidae	suspension	Cardita incrassala	B16
Mollusca	Bivalvia	Carditidae	suspension	Carditella (Carditellona) torresi	B17
Mollusca	Bivalvia	Chamidae	suspension	Chama 2	B191
Mollusca	Bivalvia	Chamidae	suspension	Chama sp. 1	B7
Mollusca	Bivalvia	Chamidae	suspension	Chamidae 1	B8
Mollusca	Bivalvia	Chamidae	suspension	Chama limbula	B85
Mollusca	Bivalvia	Corbulidae	suspension	Corbula (Notocorbula) tunicata	B11
Mollusca	Bivalvia	Corbulidae	suspension	Corbula sp. 3	B219
Mollusca	Bivalvia	Corbulidae	suspension	Hiatella australis	B52
Mollusca	Bivalvia	Crassatellidae	suspension	Talabrida sp.	B215
Mollusca	Bivalvia	Cuspidaridae	suspension	Cuspidaria sp. 1	B20
Mollusca	Bivalvia	Cuspidaridae	suspension	Cuspidaridae 1	B21
Mollusca	Bivalvia	Cuspidaridae	suspension	Cuspidaridae 2	B48
Mollusca	Bivalvia	Donacidae	suspension	Donax (Tentidonax) veruinus	B195
Mollusca	Bivalvia	Donacidae	suspension	Donax sp. 1	B212
Mollusca	Bivalvia	Galeommatidae	suspension	Scintillona sp.	B185
Mollusca	Bivalvia	Galeommatidae	suspension	Mysella sp. 1	B210
Mollusca	Bivalvia	Galeommatidae	suspension	Tellimya sp.	B217
Mollusca	Bivalvia	Graphaeidae	suspension	Hyotissa hyotis	B99
Mollusca	Bivalvia	Laternulidae	suspension	Laternula rostrata	B190
Mollusca	Bivalvia	Limidae	suspension	Limaria sp. 1	B24
Mollusca	Bivalvia	Limopsidae	suspension	Limopsis sp. 3	B200
Mollusca	Bivalvia	Limopsidae	suspension	Limopsis sp. 2	B201
Mollusca	Bivalvia	Lucinidae	suspension	Linga sp.	B193
Mollusca	Bivalvia	Lucinidae	suspension	Lucinidae 1	B214
Mollusca	Bivalvia	Lucinidae	suspension	Antigona (Antigona) lamellaris	B216
Mollusca	Bivalvia	Lucinidae	suspension	Anodontia omissa	B26
Mollusca	Bivalvia	Lucinidae	suspension	Bivalvia 45	B72
Mollusca	Bivalvia	Mactridae	suspension	Lutraria sp.	B207
Mollusca	Bivalvia	Mactridae	suspension	Mactra (Nannomactra) sp. 2	B208
Mollusca	Bivalvia	Mactridae	suspension	Mactra sp. 3	B213
Mollusca	Bivalvia	Mactridae	suspension	Mactra abbreviata	B28
Mollusca	Bivalvia	Malleidae	suspension	Malleidae 1	B32

Phylum	Class	Family	Diet	Species	Code
Mollusca	Bivalvia	Mesodesmatidae	suspension	Paphies cunata	B34
Mollusca	Bivalvia	Mesodesmatidae	suspension	Pahies heterodon	B35

Appendix 3. Photographic plates depicting 442 of the 466 benthic organisms collected from Port Curtis during 2002.

V5 - Anthozoa 11

V28 - Anthozoa 19

K2 - Polyplacophora 2

V9 - Anthozoa 4

V29 - Anthozoa 20

K6 - Chitonidae 1

V21 - Ceriantharia 3

V30 - Anthozoa 21

K7 - Acanthochitonidae 1

V25 - Anthozoa 17

N7 - Nemertea 9

K8 - Chitonidae 2

V26 - Ceriantharia 4

K1 - Polyplacophora 1

G9 - Atys cylindricus

G10 - *Cyclinna* sp. 1

G48 - *Fissurellidae* 1

G74 - *Nassarius* sp. 3

G11 - *Haminoea wallasi*

G61 - *Marginella* sp. 1

G75 - *Nassarius* sp. 4

G16 - *Trigonostoma obliquata*

G63 - *Bedeva hanleyi*

G82 - *Plicarularia burchardi*

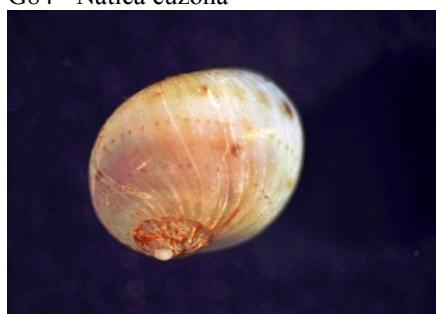

G20 - *Collumbellidae* 1

G71 - *Nassarius dorsatus*

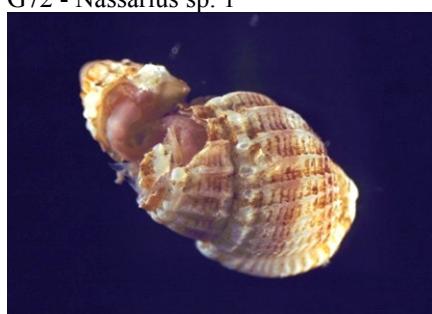

G84 - *Natica eu zona*

G40 - *Epitonium* sp. 4

G72 - *Nassarius* sp. 1

G86 - *Neverita* sp. 1

G89 - Naticidae 3

G115 - Gastropoda 46

G200 - Gastropoda 162

G91 - Naticidae 5

G154 - Gastropoda 113

G203 - Gastropoda 165

G94 - Polinices sp. 1

G168 - Gastropoda 129

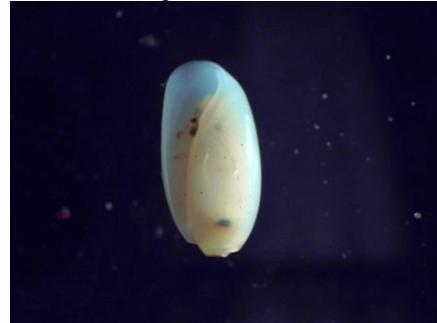

G209 - Gastropoda 171

G98 - Neritina ovalaniensis

G184 - Gastropoda 146

G226 - Potamididae 1

G106 - Gastropoda 8

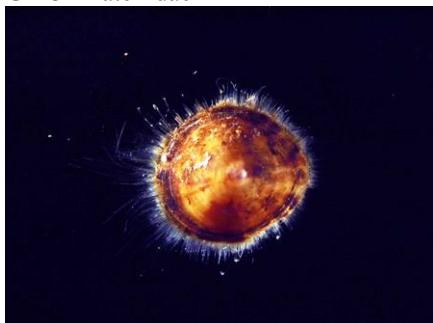

G191 - Gastropoda 153

G231 - Potamididae 8

G243 - Patellidae 1

G272 - Turritellidae 1

G293 - Tudivasmus armigera

G245 - Rissoidae 1

G273 - Turritella sp. 1

G294 - Polinices didyma

G251 - Notosinister maculosa

G289 - Gastropoda 184

G295 - Natica collei

G254 - Euchelus atratus

G291 - Mitrella sp. 1

B1 - Corbula (Serracorbula) crassa

G258 - Trochidae 18

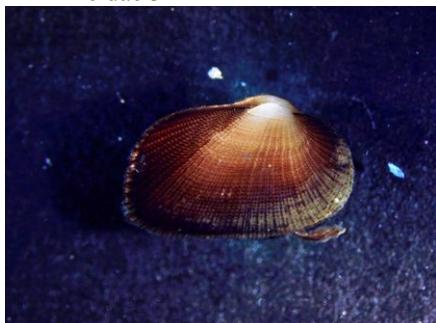

G292 - Conus aureus

B2 - Arcidae 1

B4 - Arcidae 3

B16 - Cardita incrassala

B26 - Anodontia omissa

B5 - Trisidos tortuosa

B17 - Carditella (Carditellona) torresi

B28 - Mactra abbreviata

B7 - Chama sp. 1

B20 - Cuspidaria sp. 1

B32 - Malleidae 1

B8 - Chamidae 1

B21 - Cuspidaridae 1

B34 - Paphies cunata

B11 - Corbula (Notocorbula) tunicata

B24 - Limaria sp. 1

B35 - Pahies heterodon

B36 - Myadora sp. 1

B48 - Cuspidaridae 2

B62 - Bivalvia 35

B40 - Modiolus sp. 1

B52 - Hiatella australis

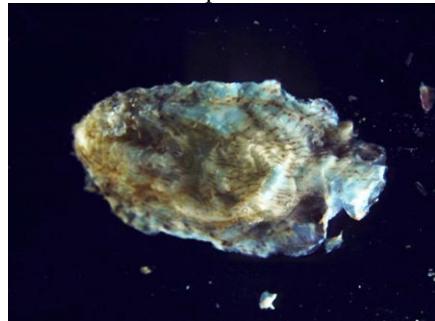

B69 - Bivalvia 42

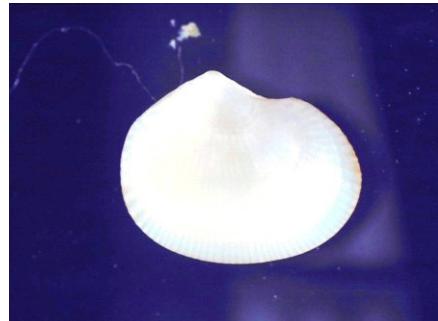

B41 - Mytilidae 1

B55 - Saccostrea sp.

B72 - Bivalvia 45

B43 - Cryptoma sp. 1

B56 - Tawera subnodulosa

B77 - Tellina (Pistris) serricostata

B45 - Nuculana darwini

B58 - Grafrium transversarium

B78 - Bivalvia 51

B80 - Bivalvia 53

B105 - Bivalvia 78

B129 - Soletellina sp. 1

B85 - Chama limbula

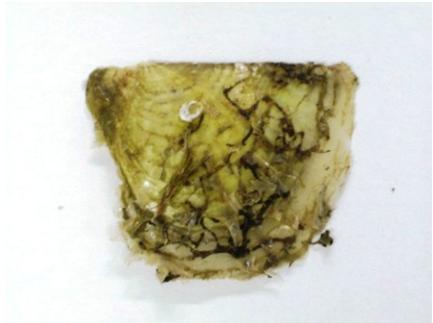

B119 - Mimachlamys gloriosa

B131 - Leionuculana superba

B98 - Pinctada maculata

B125 - Pinctada sp. 1

B132 - Soletellina petalina

B99 - Hyotissa hyotis

B127 - Gari sp. 1

B133 - Azorinus sp. 1

B101 - Bivalvia 74

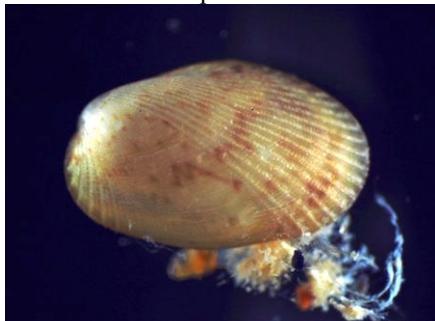

B128 - Gari sp. 2

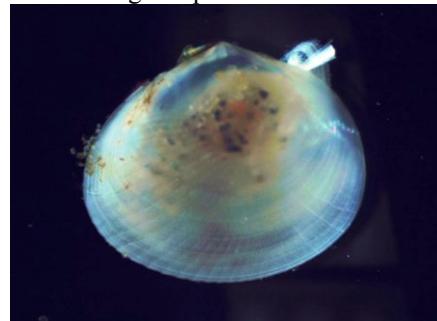

B134 - Azorinus sp. 2

B135 - Azorinus sp. 3

B148 - Strigilla sp. 1

B154 - Tellina sp. 6

B138 - Solecurtidae 1

B150 - Tellina sp. 2

B155 - Tellina sp. 7

B140 - Pharella wardi

B151 - Tellina sp. 3

B162 - Antigona materna

B141 - Solen sp. 1

B152 - Tellina sp. 4

B164 - Veneridae 1

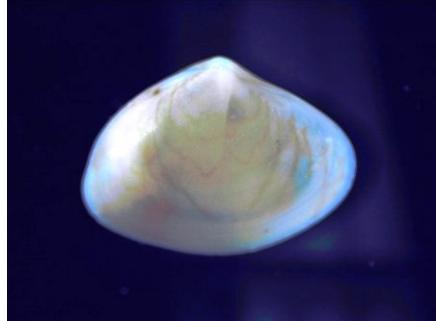

B147 - Strigilla euronia

B153 - Tellina sp. 5

B165 - Veneridae 2

B166 - Veneridae 3

B176 - Paphia undulata

B184 - Ostrea edulis

B169 - Timaclea (Timaclea) infans

B178 - Nuculana corbuloides

B185 - Scintillona sp.

B170 - Paphia sp. 1

B181 - Mytilidae 2

B186 - Circe sulcata

B174 - Pitar trevori

B182 - Nuclana (Scaeeda) crassa

B187 - Tellina sp. 14

B175 - Placamen tiara

B183 - Crassostrea gigas

B188 - Paphia exarata

B189 - *Brachidontes subramosa*

B195 - *Donax (Tentidonax) veruinus*

B200 - *Limopsis sp. 3*

B190 - *Laternula rostrata*

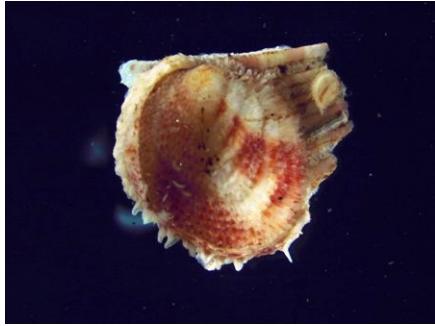

B196 - *Myadora pulleini*

B201 - *Limopsis sp. 2*

B191 - *Chama 2*

B197 - *Globivenus embrithes*

B202 - *Gari sp.3*

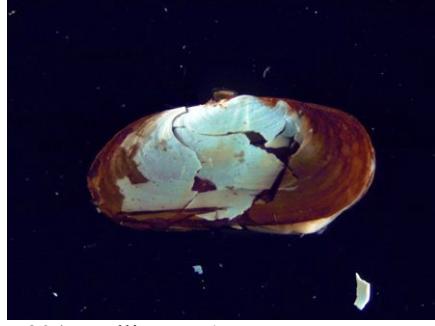

B193 - *Linga sp.*

B198 - *Timoclea lionata*

B203 - *Azorinus minutus*

B194 - *Soletellina sp. 2*

B199 - *Gari gracilenta*

B204 - *Tellina sp. 15*

B205 - *Gari weinkauffi*

B211 - *Tellina (Cadella) diluta*

Appendix 4. Summary list of species abundances (N) collected from 149 sampling stations in Port Curtis during 2002. A total of 3 * 0.1m² replicate grab samples were collected at each station during the survey (the absence of any replicates in this list indicates that no fauna were identified from the respective grab). All species codes given here refer to type material lodged in the Central Queensland University marine reference collection in Gladstone.

Appendix 6. Summary table of environmental parameters measured at 149 macrobenthic sampling station in Port Curtis during 2002. All measures presented for water temperature (°C), salinity (ppt), dissolved oxygen (mg/L) and pH, are means derived for the water column at each station (1m intervals), and have been standardised by daily readings at navigation buoy A8. Secchi depth (m) and measures of total chlorophyll (µg/L) are individual surface measurements, but have also been standardised by daily readings at buoy A8. Percentage organic carbon measures are given for surface sediments at all stations, and are means derived from three replicate grabs.

Station	Latitude	Longitude	Date	% Organic C	Temperature	Salinity	DO	pH	Secchi	Total Chl
